

Multipurpose Particle System Shader (v1.0.0)

https://docs.google.com/document/d/1ACa-sUP1HyQYmYxgAQXdIEVhPf3hAKR4bvN_PsZexaY/edit?usp=sharing

This is a guide to use and understand the multi feature shader from the Unity package.

The shader “zyn_shd_multifeature” is used to create materials that is driven by Unity’s shuriken particles.

- This shader is to be used with the Unity Shuriken particle system.
- This shader allows streaming data from the particle system to the material.

Using the Material with Unity Particle System

After creating a material with the shader, assign it to the Unity particle system.

In the Unity particle system, scroll to “Custom Data” module, hit on the dropdown and select “Vector”.

Scroll to the “Renderer” module, check “Custom Vertex Streams”.

Add “Custom1.xyzw” and “Custom2.xyzw” to the list to allow streaming of custom data.

Under the Renderer module in the Unity Shuriken particle system, add custom1 and custom2 in order to gain access to vertex streaming.

Distortion

To achieve distortion effect, additional setup is required.

- Open “Tags & Layers” window, add a new “Distortion” layer.

- Select the current Universal Render Data.
- Click on “Add Renderer Feature”.
- Select “Render Objects”.
- Rename the Render Layer.
- Change Event to “AfterRenderingTransparents”.
- Change Queue to “Transparent”.
- Uncheck the “Distortion” in Layer Mask.
- When creating the distortion material, set its layer to “Distortion”.
